Q: Why is there a difference between a single enigma variable and a batch of enigma variables? I'm currently doing some work for the first time using an enigma solver. So in the library I've been given a single, un-named variable with a list of potential solutions. I'm wondering, what is the point of having a list of variables, rather than just one? Is there any particular benefit to this? A: Taking on the first of your 3 questions: Is there any particular benefit to this? A few reasons come to mind. One is that the sharing of the potential solutions. If the number of potential solutions is large (or the time needed to evaluate them is large) then it may be a worthwhile to share them between variants. But sharing solutions does not come automatically, you have to decide if it is desirable. You may also want to have (diverse) parts of the solution in the different variants. For example, you may use some variables to model physics laws, some others to describe the sensors, etc. Third, if you have a different number of unknowns in each variant, you may work on one model until you find a solution, and then extract it and reuse it in the others. Finally, adding new variables may lead to a better description of your problem. For example, a constraint among some variables may lead to a good description of a problem for which you may not have thought. And many other reasons.
